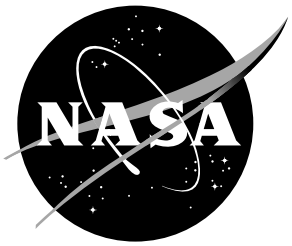
NASA STI Program. . . in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA scientific and technical information (STI) program plays a key part in helping NASA maintain this important role.

The NASA STI Program operates under the auspices of the Agency Chief Information Officer. It collects, organizes, provides for archiving, and disseminates NASA's STI. The NASA STI Program provides access to the NASA Aeronautics and Space Database and its public interface, the NASA Technical Report Server, thus providing one of the largest collection of aeronautical and space science STI in the world. Results are published in both non-NASA channels and by NASA in the NASA STI Report Series, which includes the following report types:



- TECHNICAL PUBLICATION. Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.
- TECHNICAL MEMORANDUM. Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- CONTRACTOR REPORT. Scientific and technical findings by NASA-sponsored contractors and grantees.
- CONFERENCE PUBLICATION. Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.
- SPECIAL PUBLICATION. Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- TECHNICAL TRANSLATION. English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services also include organizing and publishing research results, distributing specialized research announcements and feeds, providing information desk and personal search support, and enabling data exchange services.

Overview

This is the second volume of the final report for the Blade Displacement (BD) measurements taken during the National Full-Scale Aerodynamics Complex (NFAC) UH-60A Airloads Test. Selected plots and data for all of the primary blade displacement data sets are presented. Plots and data are also included for selected secondary data sets and for several reference data sets where the rotor was set to a common reference condition. The BD data presented here are averages derived from multiple image sets and have estimated corrections applied that account for registration errors due to blade elasticity. This document comes with a companion, text-file database that has this same averaged data formatted as comma separated values (cvs), along with the data for the individual image sets and the values of the corrections used.

Due to the large number of pages in this volume of the report, it is only intended to be used as an electronic document. (Printing it out in its entirety would require several reams of paper, so it is not recommended.) Most PDF readers should be able to display this document and allow use of the Table of Contents to quickly navigate to any desired chapter or section. Navigation sidebars, such as the one shown in Figure A for Adobe Acrobat Reader, are another convenient method for rapid navigation of this document. In some PDF readers, such as Preview for Apple OS X, using the up and down arrow keys within the sidebar enables a fast, movie-like iteration over the plots.

Data Issues

While the BD team has high confidence in most of the data presented here, there are a couple of caveats. First, the estimate lag angle values may have significant offset errors due to the potential that the rotor azimuth values used in data reduction may have had errors of 1 to 2 degrees. This was initially suspected because the estimated lag values differed by 1 to 2 degrees from the lag measured using hub mounted instrumentation. Examination of targets on the instrumentation hat, as presented in Volume I: Appendix E.3, show run-to-run discrepancies of hat target locations for identical rotor azimuth values. This indicates that there may be an issue with the value of the rotor azimuth used in reducing the data. The source of this discrepancy is not known, but it may be due to a time lag in either receiving the azimuth value from the wind tunnel data system or in triggering the photogrammetry data acquisitions. This may be correctable by using the hat targets to determine azimuth, but this process was not developed due to time and resource constraints.

The second caveat is that there are occasional data outliers. Some of these may be due to centroiding errors, but an effort was made to find and correct most of these. A second source of outliers in spanwise deformation data is

when the data is determined from more than one set of camera combinations. Each camera calibration has bias errors, which lead to bias errors in target positions determined for each set of camera combinations. When the same set of cameras is used for all targets on a blade, they have a common bias error. This common bias error will affect pitch, flap, and lag estimates, but should not affect the spanwise variation of elastic deformation estimates. However, if the inboard targets use one set of cameras and the outboard targets use a different set of cameras, the different bias errors for the two sets may cause a discontinuity in the spanwise distribution of estimated target positions, which results in a discontinuity in the spanwise variation of elastic deformation estimates. For most of the data presented, only one set of cameras was used for all targets on a blade for a specific azimuth and test condition. However, there are some cases where all the targets were not visible to each camera, so more than one camera combination was used to get data for all of the visible targets. In these cases the differing bias errors can result in discontinuities in the spanwise variation of elastic deformation estimates.

Be aware that if outliers are present in the first few spanwise radial stations of the elastic deformation data for a blade, their presence may lead to errors in the corresponding estimates of the pitch, flap, and lag angles.

Refer to Volume I for more information on data issues.

1 Geometry

This chapter gives a quick overview of the geometric definitions and procedures used for the data presented in the following chapters. For more extensive information, please refer to Volume I.

Blade Position and Orientation

For the UH-60A Airloads Wind Tunnel Test, the rotor hub and blades were mounted to the Large Rotor Test Apparatus (LRTA), which was mounted on struts in the wind tunnel test section. The tail strut was extended or retracted to change the angle of attack, α. The test section turntable was not used to change the yaw angle. Geometrically, all measurements are referenced to the center and plane of rotation of the rotor hub. When the LRTA is at a nonzero angle of attack, the reference coordinate system moves with the hub center and its plane of rotation as they are rotated about ball sockets on the main strut tips. The UH-60A has four rotor blades numbered 1 through 4 as shown in Fig. 1.1. The rotor hub/shaft rotation angle or shaft azimuth, ψ_{shaft}, is defined as zero when the principal quarter-chord line of blade 1, at zero lag angle, is aligned with the aft centerline of the LRTA. Blade position and orientation are defined by four rigid body rotation angles applied with respect to the reference orientation of each blade at 0° azimuth. These four angles, in the order of application, are pitch, θ, flap, β, lag, ζ, and blade azimuth, ψ.

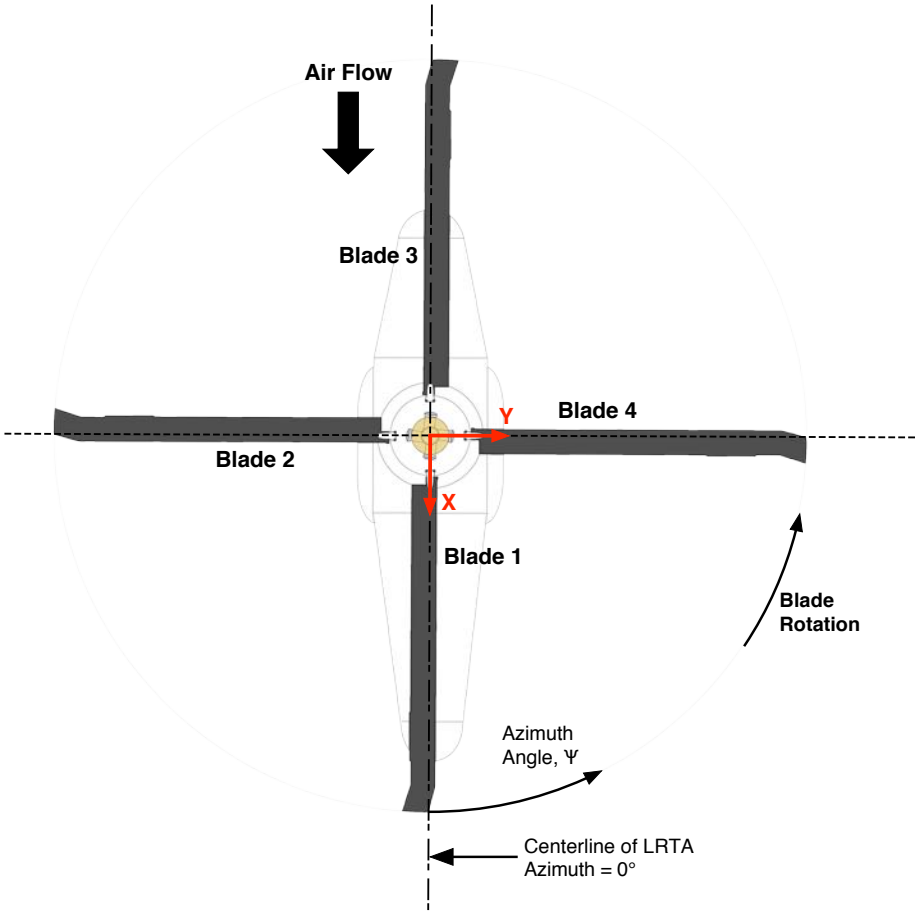

Figure 1.1. Top view schematic of UH-60A rotor installation.

To show how these angles are defined, a simplified representation of the rotor blade is used. The UH-60A rotor blade has a complex shape with the airfoil profile, twist, and sweep all varying along the span. However, pitch, flap, lag, and later, deformations, can be thought of as being applied to a rectangular cylinder or bounding box that encompasses the blade in 3-D space. Figure 1.2 shows an end view of this bounding box with a selection of the UH-60A airfoil profiles from different radial stations. Pitch, θ, is the first rotation angle applied to a blade's

reference geometry. As shown in Fig. 1.3, the blade is rotated in the vertical yz plane about its quarter-chord line, which is coincident with the x-axis of the hub coordinate system. Second, the blade is rotated in the vertical xz plane about its hinge point by the flap angle, β, is shown in Fig. 1.4. Third, is a horizontal rotation about the hinge point by the lag angle, ζ, as shown in Fig. 1.5. Finally, the blade and hub are rotated together in the hub rotation plane about the hub center by the blade azimuth angle, ψ, as shown in Fig. 1.5.

Elastic Blade Deformations

Elastic blade deformation variables represent the subtraction, in the blade reference coordinate system, of rigid blade geometry from the measured, elastically deformed blade geometry. These variables, Δx, Δy, Δz, and Δtwist, are defined for the locations along the quarter chord as shown in Fig. 1.6. It is assumed that the rigid blade and the elastically deformed blade have the same pitch, flap, lag, and azimuth orientation at the blade root. Errors in the estimated blade root orientation propagate into errors in the elastic deformation variables.

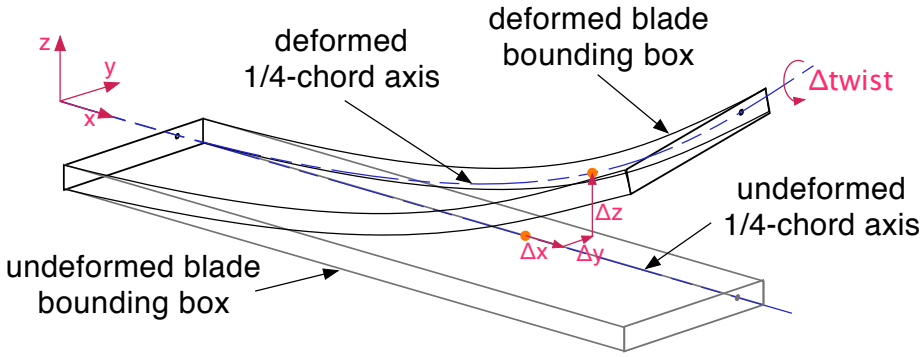

Figure 1.6. Deformation variable definitions.

Position and Orientation Errors Due to Blade Elasticity

The photogrammetry system measures the 3D locations of registration targets on each blade. The approximate locations of these targets in the blade reference coordinate system is shown in Fig. 1.7. The first four inboard rows of targets are used to estimate the pitch, flap, and lag of a blade from the measured target locations. The blade azimuth is first determined from the blade number and the shaft azimuth provided by a transducer on the rotor shaft. Then a least-squares regression is used to determine the pitch, flap, and lag angles that provide the best transformation of the reference target positions for the first four rows of targets to match the corresponding measured target positions. This provides the initial, uncorrected pitch, flap, and lag values.

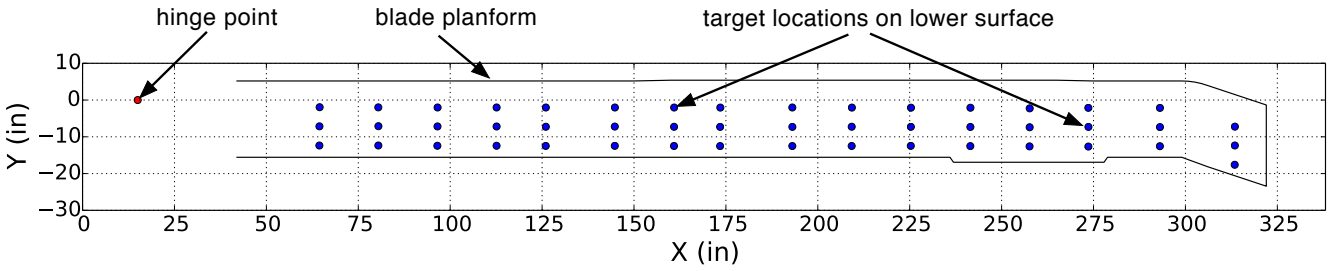

Figure 1.7. Horizontal position of photogrammetry targets in blade reference coordinates.

Due to elastic deformation of the measured blade, this registration process can lead to errors in the estimated blade position and orientation. This is illustrated in Fig. 1.8, which shows a hypothetical registration to estimate the flap angle. The green xz axes show the actual flap angle, β_{actual}, and the green line represents the deformed quarter-chord line of the measured blade. The dots along the line represent registration target rows. The blue xz axes show the estimated flap angle, $\beta_{estimated}$, that is found when fitting the reference target locations for the first four rows to the corresponding measured target locations. The difference in these two angles is the flap angle error due to blade elasticity. Similar errors occur for pitch and lag.

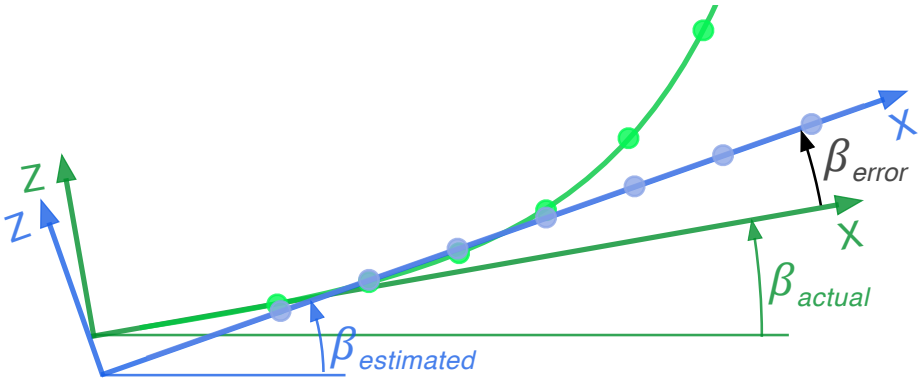

Figure 1.8. Illustration of flap angle estimate error due to blade elasticity.

The data presented in this document have had corrections applied to account for these errors. These corrections are based on the following assumptions and procedures.

1) For the pitch angle correction, it is assumed that Δtwist is zero at the hinge point and that the first derivative of Δtwist with respect to x is also zero at the hinge point. The pitch angle correction is based on a cubic fit of the inital Δtwist estimates for the first three inboard rows. Application of pitch angle correction results in a zero value for Δtwist at the hinge point.
2) For the flap angle correction, it is assumed that Δz is zero at the hinge point and that the first and second derivatives of Δz with respect to x are also zero at the hinge point. The flap angle correction is based on a cubic fit of the Δz estimates for the first five inboard rows after the pitch angle correction has been applied. Both a flap angle correction and a Δz correction are determined. The Δz correction is determined and applied to enforce a zero value for Δz at the hinge point.
3) For the lag angle correction, it is assumed that Δy is zero at the hinge point and that the first and second derivatives of Δy with respect to x are also zero at the hinge point. The lag angle correction is based on a cubic fit of the Δy estimates for the first five inboard rows after the pitch, flap, and Δz corrections have been applied. Both a lag angle correction and a Δy correction are determined. The Δy correction is determined and applied to enforce a zero value for Δy at the hinge point.

Note that no corrections have been determined for or applied to the Δx values.

2.6.2 Spanwise Elastic Deformations

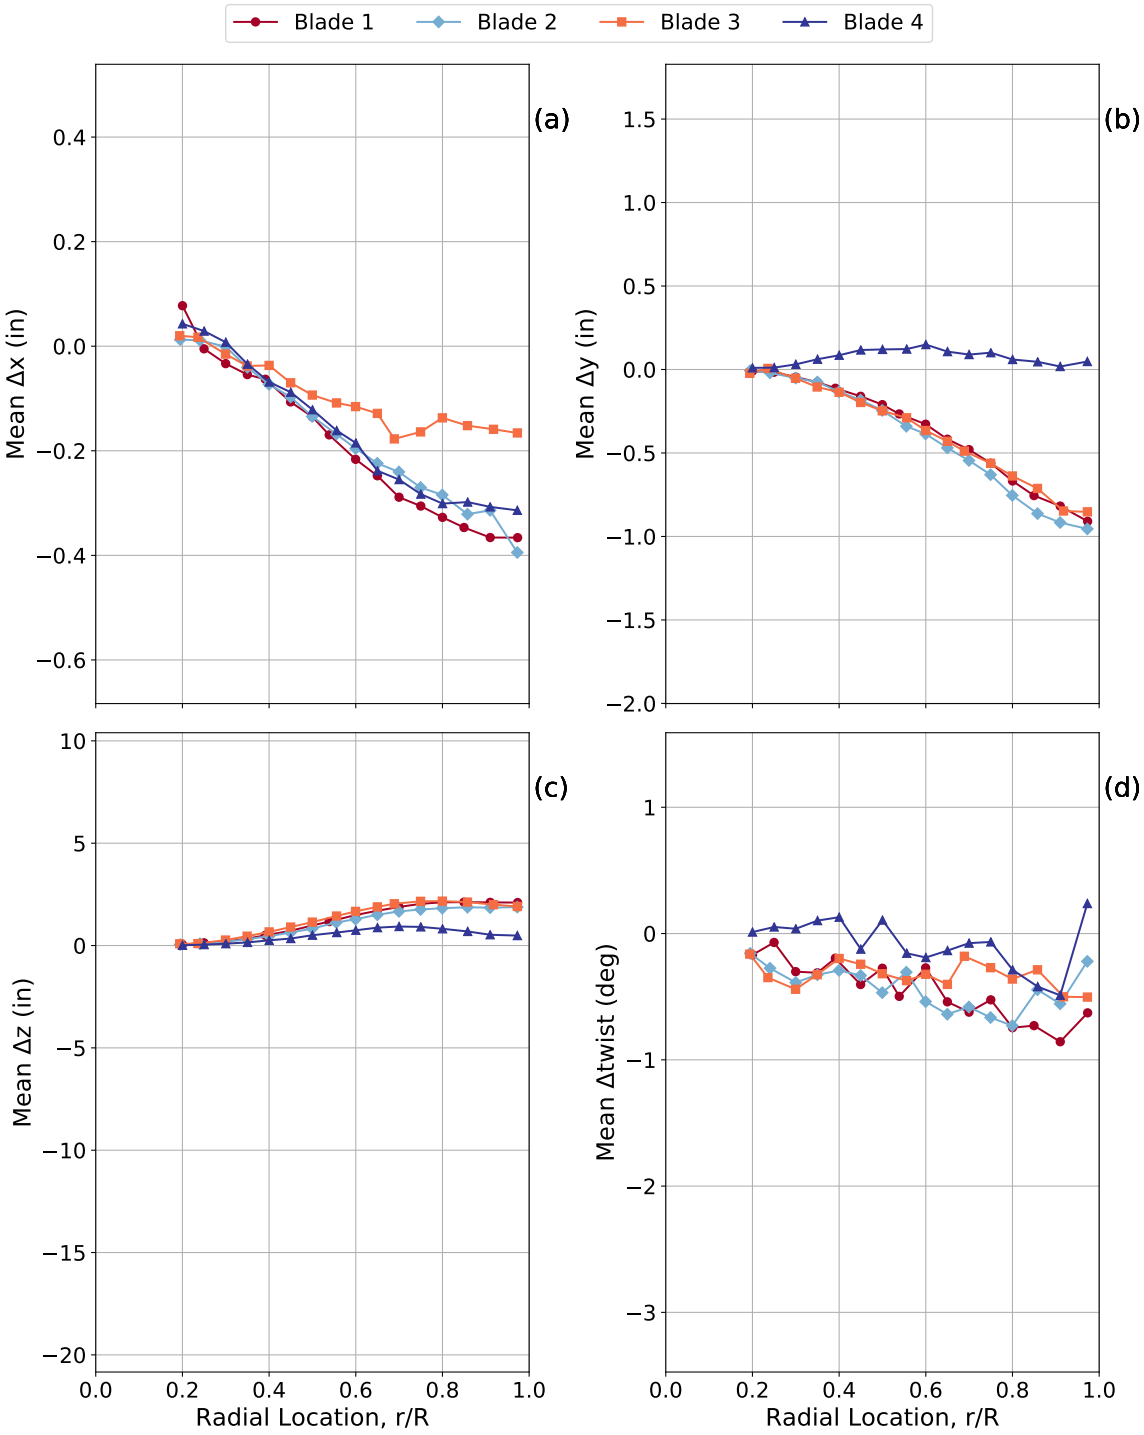

Figure 2.6-2. 0° azimuth, spanwise blade deformations,
(a) mean Δx, (b) mean Δy, (c) mean Δz, (d) mean Δtwist.
$C_T/\sigma = 0.1$, $\mu = 0.3$, $\alpha = -0°$
NFAC run 42, points 60 to 63. BD run 19, points 1263 to 1302.

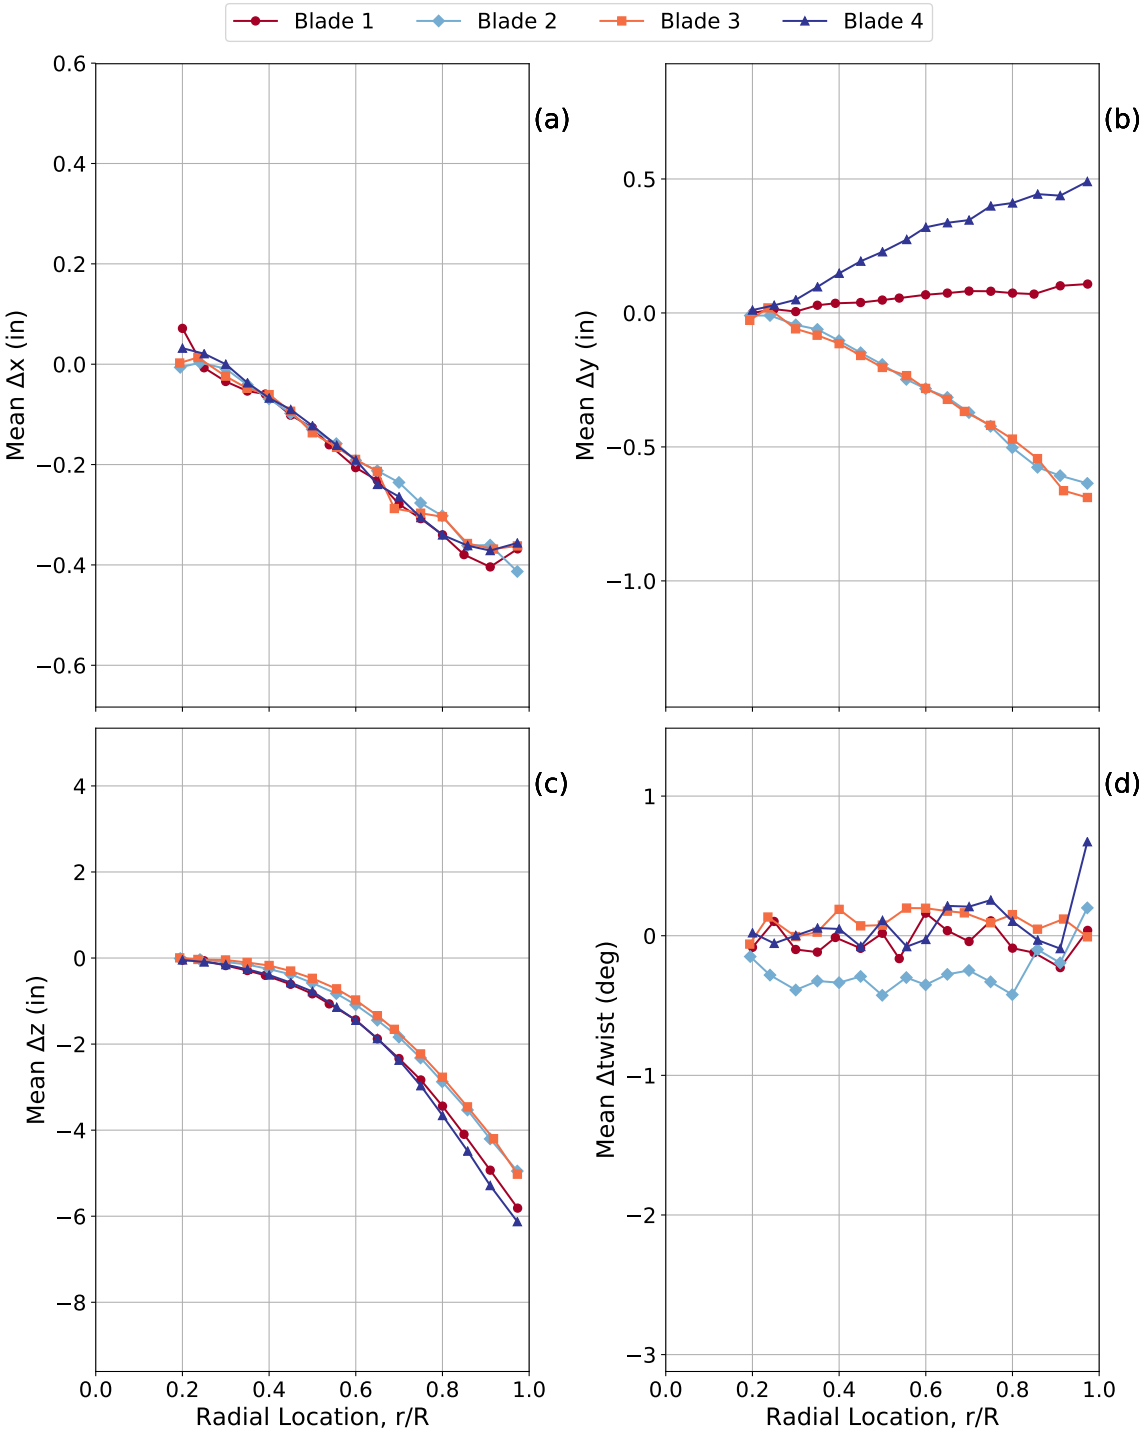

Figure 2.8-3. 5° azimuth, spanwise blade deformations,
(a) mean Δx, (b) mean Δy, (c) mean Δz, (d) mean Δtwist.
C_T/σ = 0.08, μ = 0.15, α = -4°
NFAC run 43, points 28 to 31. BD run 20, points 1587 to 1626.

Table 2.8-6. 5° azimuth - spanwise blade deformations.
$C_T/\sigma = 0.08$, $\mu = 0.15$, $\alpha = -4°$
NFAC run 43, points 28 to 31. BD run 20, points 1587 to 1626.
